(54) Solid formulations containing pheromones

(57) A solid formulation comprising a sex insect pheromone as an active substance supported on an inert carrier material coated with a film-forming resin, an adhesive, a U.V. stabilizer, an antioxidant and a dispersing and/or wetting agent, the formulation having the following composition:

pheromone	0.5 to 10% by weight
film-forming resin	5 to 30% by weight
dispersing agent + wetting agent +adhesive	5 to 15% by weight
U.V. stabilizer	0.5 to 10% by weight
antioxidant	0.5 to 10% by weight
inert carrier	to make 100% by weight.

The formulations are used for the control of insects in the form of wettable powders.

SPECIFICATION

Solid formulations containing pheromones

5	The present invention relates to solid formulations containing pheromones, and in particular to solid formulations containing as an active ingredient a sex pheromone of an insect supported by an inert material coated with a film-forming resin. The formulations are useful for hindering the mating of insects (mating disruption).	5
10	In recent years pheromones have become very important in the research for methods useful to control	10
15	Pheromones are secreted outside the insect body and may be divided into classes depending on the type of reaction they induce, e.g. aggregation, tracing, sexual and alarming pheromones. The most diffused and interesting pheromones for use in the control of insects are the sex pheromones	15
20	which are most frequently secreted by females than by males, and attract the individuals of the opposite sex for mating. The use of pheromones for controlling the insects is based on the principle that small quantities of such compounds, obtained by synthesis, cause the same reactions as are induced by the male or female insects secreting the natural attractant.	20
25	In practice, the synthetized sex pheromones are used both to survey the development of the harmful species' population and to control the harmful species by mating disruption. The former type of application permits monitoring by means of periodical samplings with small cage-traps, of the density variations of the harmful insect population in order to forecast the time in which	25
	the "harmfulness threshold" will be reached. In the latter type of application, the sex pheromones are directed to partially or fully substitute the insecticides and to directly control the insects by modifying their behaviour (mating disruption). There are two techniques for controlling insects using pheromones: mass trapping and confusion. The	
30	former technique (mass trapping) is directed to attract and to catch as many insects as possible by means of small cage-traps. The latter technique (confusion technique) consists in spreading the pheromone in the atmosphere in such a way as to render the males or females uncapable of "feeling" and locating the individuals of the opposite sex, so hindering mating.	30
35	In practice, the pheromone can be diffused by distributing the product at various properly spaced points of the infested area, or by uniformly spraying it on the whole cultivation. In the first case use is made of evaporators containing the pheromone, which is included or incorporated in materials of various natures suited to make volatilization occur at the proper and constant rate. However, this method is rather expensive	35
40	because of the high cost of both evaporators and the labour involved. A less expensive and complicated method is that of distributing the pheromone all over the area by spraying from the ground or from the air using special controlled-release formulations. Slow-release formulations systems containing pheromones are known. Examples of such systems include	40
	aqueous suspensions of pheromone-containing micro-capsules having walls made of polyamides as disclosed in United States Patent Specification No. 3 577 515 or of gelatin as disclosed in United States Patent Specification No. 2 800 457 and 2 800 458; multi-layer polymeric systems containing pheromone as disclosed in A.C.S. 33, 1976 page 283, and hollow fibre systems consisting of capillaries with an open end	45
45	through which the pheromone volatilizes as disclosed in United States Patent Specification No. 4 017 030. Such systems require a sophisticated technique both for their preparation and for successive distribution in the field. A further disadvantage exhibited by some of these systems consists in supplying a release	73
-50	composition of the capsules and by the chemical composition of the other formulation components, but also by environmental factors such as temperature, light and moisture. The desired requisite for a formulation that will release a sufficient quantity of pheromone to permeate the air and achieve the effect of inhibiting	50
55	the mating, is a controlled, total and constant release for an adequate period of time. The invention has been made with the above points in mind.	55

55

Therefore according to the present invention there is provided a solid formulation comprising a sex insect pheromone as an active substance supported on an inert carrier material coated with a film-forming resin, an adhesive, a U.V. stabilizer, an antioxidant and a dispersing and/or wetting agent, the formulation having the following composition:

5 5 pheromone 0.5 to 10% by weight film-forming resin 5 to 30% by weight dispersing agent + wetting agent + adhesive 5 to 15% by weight U.V. stabilizer 0.5 to 10% by weight 10 10 antioxidant 0.5 to 10% by weight inert carrier to make 100% by weight.

It has been observed that the formulations containing the active substance supported by an inert carrier give rise to a linear and total but fast release of the pheromone. However, formulations containing the active substance supported on inert carriers coated with film-forming resins according to the invention give rise to a controlled and total pheromone release which is approximately linear.

The release rate of the active substance is a function of both the chemical class of the chosen resin (given that for the different polymers the migration speed of the active substance is different in each case) as well as of the quantity of deposited resin.

Suitable, film-forming resins, for use in this invention, include carboxylated polyvinyl-alcohol-based compounds, compounds based on terpene polymers and mixtures of chlorinated derivatives of natural rubber.

In the formulations of the invention it is essential that a U.V. stabilizer and an antioxidant are present for protecting the chemical integrity of the active substance to enhance the stability of the pheromone in the formulation as well as to preserve the pheromone itself for as long as possible when the field treatment is carried out.

Suitable U.V. stabilizers include benzophenone derivatives having a high molecular weight. A preferred U.V. stabilizer is 2-hydroxy-4'-octyloxy-benzophenone of the formula:

Suitable antioxidants include derivatives of 2,6-di-terbutylphenol, e.g. stearyl 2,6-di-terbutylphenol propionate and pentaerythrite 2,6-di-terbutylphenol propionate.

Examples of wetting agents and adhesives suitable for use in the formulations are compounds based on 40 mixtures of methacryl polymer and nonylphenol poly-oxyethylates; suitable dispersing agents are compounds based on sodium ligno-sulphonate.

The formulations of this invention may be prepared by conventional mixing techniques.

The formulations of this invention may be applied as a wettable powder by conventional methods for application to agricultural cultivations.

The sexual pheromones for use as the active substance in the formulatings of the invention include pheromones of different insects, e.g. (E)-11-tetradecenale, pheromone of Choristoneura fumiferana; (E,E)-8, 10-dodecadienol, pheromone of Laspeyresia pomonella L.; (Z)-8-dodecylacetate, pheromone of Grapholitha molesta, Busk.; (Z)-9-dodecenyl acetate, pheromone of Clysia ambiguella Hb.; (E,Z)-7,9-dodecadienyl acetate, pheromone of Lobesia botrana Den & Schiff; (Z)-11-tetradecenyl acetate and (E)-11-tetradecenyl acetate, pheromone of Archips podanus Scop.; (Z-E)-9,11-tetradecadienyl acetate, pheromone of Spodoptera littoralis Boisd.; (Z)-11-hexadecen-1-ale, pheromone of Heliothis armigera HB., (Z,E)-7,11-hexadecadienyl acetate; and (Z,Z)-7,11-hexadecadienyl acetate phermone of Pectinophora gossypiella.

Suitable inert carrier materials on which the active ingredient is supported include calcined fossil meal, kaolin, micronized attapulgites and talc. The fossil meal comprises a composition based on AI, Fe, Ca, Mg, Solicates and is available under the trade names Celite SSC and Celite 209. Kaolin comprises compositions based on aluminum silicate and is available under the trade name Argirek B22. Attapulgite comprises compositions based on AI, Mg, Ca, Fe, Na, K silicates and is available under the trade name Diluex.

Preferred formulations in accordance with the invention having the following compositions:
--

5	pheromone film-forming resin dispersing agent adhesive U.V. stabilizer antioxidant inert carrier	5% by weight 15% by weight 5% by weight 10% by weight 5% by weight 5% by weight 5% by weight	5

25	inert carrier	50% by weight	25

The formulations of the invention have the advantage that they may be applied by methods and equipment already used for wettable powders, with appreciable economical advantages and ease of handling for any user.

30 The invention will now be illustrated by the following Examples.

30

35

EXAMPLE 1

This Example illustrates the tests for determining the most suited stabilizers.

100 g of the compositions from 1 to 10 as reported in Table I, were prepared by precipitating from a solution in CH₂Cl₂ the active substance (a.s.) and selected stabilizers on a pre-selected carrier and thereafter allowing the solvent to evaporate.

50 g of such compositions were maintained for 14 days at room temperature and 50 g of the compositions were kept at a thermostatically stabilized temperature of 40° C. At the end of this period the residual a.s., after extraction with n-hexane, was evaluated by gas liquid chromatography.

EXAMPLE 3

Preparation of complete formulations

100 g of formulations 14, 15 and 16, reported in Table V, were prepared by precipitating from a solution in CH₂Cl₂ the a.s., the stabilizers and the resin onto the powdered carrier. Thereupon the solvent was allowed to evaporated at room temperature and the wetting agent, dispersing agent and adhesive and admixed to the composition. The resulting mixture was then homogenized by passing it through a suitable mechanical mixer.
